# I. INTRODUCTION

The Platte River Recovery Implementation Program (Program) was initiated on January 1, 2007 between Nebraska, Wyoming, Colorado, and the Department of the Interior to address endangered species issues in the central and lower Platte River Basin. The species considered in the Program, referred to as "target species", are the whooping crane (*Grus americana*), piping plover (*Charadrius melodus*), interior least tern (*Sterna antillarum*), and pallid sturgeon (*Scaphirhynchus albus*).

Monitoring of central Platte River water quality near Program lands is relevant to the productivity and diversity of native fish and other aquatic species supportive of the interior least tern, piping plover, and whooping crane. Ultimately, the baseline data (2009, 2010, and 2011) will be used to assess Priority Hypotheses as described in Table 2 of the Adaptive Management Plan (AMP) (PRRIP 2006). The focus of the 2012 water quality monitoring of the central and lower Platte River for the Program has shifted from the collection of systematic "baseline" water quality data to Program action-based water quality monitoring. The action-based water quality monitoring will be used to evaluate effects of the Program's land and water management action on the water quality of the central and lower Platte River.

EA Engineering, Science, and Technology, Inc. (EA) was contracted by the Program to develop an Annual Monitoring Plan (Plan) that was implemented in 2012 in order to assess the effects of anticipated Program actions on the water quality of the Platte River. This report presents the results of the action-based water quality monitoring for the 2012 monitoring season (mid-August through early December). Data collected included: stage/discharge, water quality parameters (temperature, turbidity, dissolved oxygen, pH, and specific conductance), representative water quality samples for metals (dissolved copper, dissolved lead, dissolved nickel, total selenium, total calcium, and total magnesium), and the bacterium *Escherichia coli (E. coli)*.

## I.A. Purpose

The purpose of the action-based monitoring is to assess the effects of Program land and water management action on the water quality of the central and lower Platte River (Figure 1).

The action-based Protocol was developed to:

- Categorize what type of Program actions will be major and minor events as related to water quality.
- Define timing, duration, and location of water quality data collection before, during, and after Program actions related to the Platte River.

The action based Protocol was developed for the collection of data to:

- Determine water quality during and immediately before and after Program actions.
- Determine temporal and spatial variations in water quality related to Program actions.

- Determine via data analysis and statistical methods Program-related effects on water quality, if evident, over time.

Implementation of the action-based Protocol included:

- Collection and evaluation of data.
- Summarization of results.
- Statistical analysis of possible variation of water quality by Program actions.
- Development of recommendations for subsequent action-based water quality monitoring.

## I.B. Program Activities

The Program completed one minor and two major events in the central Platte River that required monitoring of Platte River water quality (Figure 2).

Minor Event

- Island Building. Action performed from 21 August 2012 to 27 September 2012 between the Odessa and Kearney monitoring locations. Island building was accomplished by mechanically excavating/pushing sand/gravel located within the high-banks of the Platte River to create islands at a higher elevation than current river stage.

Major Event

- Sediment Augmentation – Dyer Property. Action performed from 26 September 2012 through 30 November 2012 upstream of the Overton monitoring location. Augmentation material was produced by establishing a sand pit operation at an existing sand pit at the Dyer property. The sand pumping operation produced augmentation material that was pumped to an active river channel for disbursement.
- Sediment Augmentation – Cottonwood Ranch. Action performed from 17 September 2012 through 30 November 2012 upstream of the Odessa monitoring location. Augmentation material was produced by mechanical placement of existing material located on high areas within the river channel into active flowing areas within the Platte River channel.

# II. METHODS AND PROCEDURES

Platte River action-based water quality monitoring was designed to assess the effects of Program land and water management actions on the water quality of the central and lower Platte River. The area of interest included the central Platte River (Lexington to Chapman, Nebraska) and the lower Platte River (Chapman to confluence with the Missouri River). Water quality was measured using *in-situ* continuous water quality sondes (sondes), discharge measurements from established gaging stations, and discrete water sample collection at monitoring locations. The methods and procedures for monitoring the water quality in the central and lower Platte River adhered to the baseline Water Quality Monitoring Protocol (PPRIP 2011a, PPRIP 2011b) and Protocol Addendums (PPRIP 2012a, PRRIP 2012b). Photographs of the field work are included in Appendix D.

## II.A. Monitoring Locations

A minor Program event (island building) at one location and two major events (sediment augmentation) were completed in 2012 necessitating the monitoring of water quality in the central Platte River. The Platte River Water Quality Monitoring Protocol Addendum (PPRIP 2012) identified the Platte River monitoring locations that will be monitored before-during and after a minor/major program event (Table 1 and Figure 1). Sondes were co-located with the existing stream gaging stations.

**Table 1. Spatial Monitoring Matrix**

| Monitoring Location No. | Platte River Locations | Major Event Location | Minor Event Location | Discharge | Water Quality | Analytical |
|---|---|---|---|---|---|---|
| 1 | Lexington | X | | NDNR | EA | EA |
| 2 | Overton | X | X | USGS | EA | EA |
| 3 | Odessa | X | X | NDNR | EA | EA |
| 4 | Kearney | X | X | USGS | EA | EA |
| 5 | Shelton | X | X | NDNR | EA | EA |
| 6 | Grand Island | X | | USGS | EA | EA |
| 7 | Duncan | X | | USGS | EA | EA |
| 8 | Louisville | X | | USGS | EA | EA |

Notes:
NDNR – Nebraska Department of Natural Resources
USGS – United States Geological Survey
EA – EA Engineering, Science, and Technology, Inc.

## II.B. Parameters of Interest

Collected water quality data was categorized into three groups:

- **Discharge** – Discharge is the measurement of stream flow and is expressed as the amount of water that passes a fixed point over time and is typically represented as cubic feet per second (cfs). River stage and/or gage height was collected in feet (ft).

- **Continuous Water Quality Monitoring** – Continuous water quality data collected included: temperature, turbidity (optical sensor), dissolved oxygen by optical dissolved oxygen (ODO) and Luminescent Dissolved Oxygen (LDO) technology, pH, and specific conductance.

- **Discrete Water Quality Monitoring –** Discrete water quality monitoring was separated into two groups: metals monitoring and *E. coli* monitoring. Metals monitoring included the collection of water samples for analysis of dissolved copper, dissolved lead, dissolved nickel, total selenium, total calcium, and total magnesium. Samples were collected by EA and analyzed by TestAmerica of Cedar Falls, Iowa (a National Environmental Laboratory Accreditation Program (NELAP)-certified laboratory). *E. coli* monitoring

included analysis of water samples for *E. coli* and coliform bacteria. Monitoring for *E. coli* was performed to assess the potential for increased pathogens in the central Platte River resulting from concentrated populations of waterfowl using the central Platte River due to Program activities. Sampling events were performed during periods of peak waterfowl use (February through March) and minimal waterfowl use (July through September). Samples were analyzed by Ward Laboratories, Inc.

### II.B.1. Frequency and Duration

The index period for the collection of continuous water quality monitoring data was from 9 August 2012 through 7 December 2012. These dates were inclusive of the 2012 Minor Program event (21 August to 27 September) and Major Program events (21 September to 30 November) and included 1-week prior to and 1-week post event water quality monitoring. The frequency and duration of data collection is listed below:

- **Discharge**
  - Existing gaging stations on the Platte River are operated continuously by the USGS and NDNR. River stage was measured continuously at these stations and discharge was estimated using rating curves. A data point was collected every 15 minutes at USGS gaging stations: Louisville, Duncan, Grand Island, Kearney, and Overton. The NDNR gaging stations, Shelton, Odessa, and Lexington, collected a data point every 30 minutes.

- **Continuous Water Quality Monitoring**
  - EA installed minor event water quality monitoring sondes at Overton, Odessa, Kearney, and Shelton on 8 - 9 August 2012. Major event water quality monitoring Sondes were installed at Louisville and Grand Island on 12 September 2012. Sondes were not installed at Duncan and Lexington due to very low to no water in the Platte River at these locations. Water quality monitoring at all locations was terminated on 6 - 7 December 2012. A data point was collected every 30 minutes.

  - Following installation, operation and maintenance of the sondes (including the downloading of data) was conducted weekly (Table 2 and Table 3).

**Table 2. Dates of Minor Events; Dates and Location of Operation and Maintenance Events (2012)**

| Date | Sites |
|---|---|
| August 8 | Shelton, Kearney |
| August 9 | Odessa, Overton |
| August 13 | Shelton, Kearney, Odessa, Overton |
| August 17 | Shelton, Kearney, Odessa, Overton |
| **August 21** | **Minor Event Initiated** |
| August 23 | Shelton, Kearney, Odessa, Overton |
| August 29 | Shelton, Kearney, Odessa, Overton |
| September 5 | Odessa, Overton |
| September 6 | Shelton, Kearney |
| September 13 | Shelton, Kearney, Odessa, Overton |
| September 19 | Shelton, Kearney, Odessa, Overton |
| September 26 | Shelton, Kearney, Odessa, Overton |
| **September 27** | **Minor Event Ended** |
| October 1 | Shelton |
| October 2 | Odessa, Overton |
| October 4 | Kearney |

**Table 3. Dates of Major Events; Dates and Location of Operation and Maintenance Events (2012)**

| Date | Sites | | Date | Sites |
|---|---|---|---|---|
| September 12 | Grand Island, Louisville | | October 24 | Shelton, Kearney, Overton, Grand Island |
| September 13 | Shelton, Kearney, Odessa, Overton | | October 25 | Odessa |
| September 19 | Shelton, Kearney, Odessa, Overton, Grand Island, Louisville | | November 1 | Shelton, Grand Island, Louisville |
| **September 21** | **Major Event(s) Initiated** | | November 2 | Kearney, Odessa, Overton |
| September 26 | Shelton, Kearney, Odessa, Overton, Grand Island | | November 6 | Shelton, Kearney, Odessa, Overton, Grand Island, Louisville |
| September 28 | Louisville | | November 14 | Shelton, Kearney, Grand Island, Louisville |
| October 1 | Shelton, Grand Island | | November 15 | Odessa, Overton |
| October 2 | Odessa, Overton | | November 20 | Shelton, Kearney, Odessa, Grand Island |
| October 4 | Kearney | | November 21 | Overton, Louisville |
| October 5 | Louisville | | November 29 | Shelton, Kearney, Grand Island, Louisville |
| October 10 | Louisville | | November 30 | Odessa, Overton |
| October 11 | Shelton, Odessa, Overton, Grand Island | | **November 30** | **Major Event(s) End** |
| October 17 | Shelton, Kearney, Odessa, Overton, Grand Island | | December 6 | Shelton, Kearney, Odessa, Overton, Grand Island |
| October 23 | Louisville | | December 7 | Louisville |

- **Discrete Water Quality Monitoring (Metals)**
  - The index period for the collection of discrete water quality data was the fourth week of Program activities.
  - Representative water samples for analytical analysis of metals were collected at the eight monitoring locations listed in Table 1 on 27 October 2012.
- **Discrete Water Quality Monitoring (*E. coli*)**
  - The index period for the collection of discrete water quality data was from March through September.
  - Samples were collected from the Platte River during periods of concentrated waterfowl populations in March (peak period), and during periods with minimal waterfowl populations in September (non-peak period).
  - Representative water samples for *E. coli* were collected at Lexington, Kearney, and Grand Island on the dates listed in Table 4. A 2:1 or 5:1 and a 20:1 dilution of the sterilized water with the samples were conducted at the laboratory to obtain counts of coliform and *E. coli* colonies in 100 mL of water.

**Table 4. Date and Location of *E. coli* Sampling Events (2012)**

| Peak Period, Date | Non-Peak Period, Date |
|---|---|
| March 1 | September 5 |
| March 7 | September 12 |
| March 14 | September 20 |

## II.C. Discharge and River Stage

Platte River discharge and stage measurements were obtained from existing gaging stations maintained by the USGS and NDNR (Table 1). River stage was measured continuously at these gaging stations and discharge was estimated using rating curves. The rating curves are maintained by the owning agency (USGS or NDNR). Periodic measurements of depth and flow rate by the respective agencies are used to adjust the rating curves, as needed.

## II.D. Continuous Water Quality Monitoring

A sonde was co-located at gaging stations as described in Table 1. Two different suppliers of sondes were used to collect water quality data. The sondes collect the same data but were purchased at different times. The Hydrolab MS-5 sondes (seven units) were purchased utilizing a grant from the Nebraska Department of Environmental Quality (NDEQ). A Eureka Manta 2 (one unit) was purchased by the Program after learning a sonde deployed by the USGS at Louisville that the Program planned to obtain data from did not collect all the necessary parameters. An MS-5 was deployed at Overton, Odessa, Kearney, Shelton, and Grand Island. The Eureka Manta 2 was deployed at Louisville. Sondes were not deployed at Lexington and Duncan due to very low to no flows observed during the monitoring period. The data and units of measure collected are listed in Table 5.

**Table 5. Continuous Water Quality Parameters**

| Water Quality Parameter | Unit | Range | Accuracy | Resolution |
|---|---|---|---|---|
| **Hydrolab MS-5** | | | | |
| Temperature | Degrees Celsius | -5 to +50ºC | ± 0.10 ºC | 0.01 ºC |
| Turbidity | Nephelometric Turbidity Units | 0 to 3,000 NTU | ± 1% up to 100 NTU<br>± 3% up to 100–400 NTU<br>± 5% from 400–3,000 NTU | 0.1 NTU from 0-400 NTU<br>1 NTU for >400-3,000 NTU |
| Luminescent Dissolved Oxygen | mg/L | 0 to 30 mg/L | ± 0.01 mg/L @ ≤ 8 mg/L<br>± 0.02 mg/L @ > 8 mg/L | 0.01 or 0.1 mg/L |
| pH | Standard Units | 0 to 14 units | ± 0.2 units | 0.01 units |
| Specific Conductance | mS/cm | 0 to 100 mS/cm | ± 1% of reading; + 0.001 mS/cm | 0.0001 mS/cm |
| **Eureka Manta 2** | | | | |
| Temperature | Degrees Celsius | -5 to +50ºC | ± 0.10 ºC | 0.01 ºC |
| Turbidity | Nephelometric Turbidity Units | 0 to 3,000 NTU | 0-100 < 1% of reading<br>100-400 < 3% of reading<br>over 400 < 5% of reading | 0.1 NTU |
| Dissolved Oxygen | mg/L | 0 to 25 mg/L | 1% of reading or 0.02 mg/L, whichever is greater | ± 0.01 mg/L |
| pH | Standard Units | 0 to 14 units | ± 0.2 units | 0.01 units |
| Specific Conductance | mS/cm | 0 to 100 mS/cm | 1% of reading ± 1 count | 0.1 mS/cm |

## II.D.1. Continuous Water Quality Sonde Installation

To maintain continuity of data and to minimize variability between data sondes the same data sonde has been deployed at the same monitoring location for each of three Platte River baseline water quality monitoring periods (2009, 2010, and 2011) and the 2012 action-based water quality monitoring period. Prior to installation, each sonde was calibrated following the manufacturer's specification using calibration standards and documented on the field data sheets

(Appendix E). Each sonde was suspended on the downstream side of the bridge at the selected monitoring location. The datalogger, battery source, and sonde were housed in a section of PVC pipe (casing) and tethered to the bridge railing using heavy duty chain. The sonde was locked to the end of the chain and inserted into the casing. The cap for the casing had a hole large enough for the chain to pass through. The casing was attached to the chain by drilling a hole near the top of the casing and inserting a bolt through the casing, passing through the chain. The submerged section of the casing containing the sonde was slotted and/or perforated with circular holes and the bottom was open to prevent sediment accumulation. A second bolt was placed at the bottom of the casing to prevent the sonde from slipping through. A football-sized float was attached to the bottom of the casing to keep the sonde suspended just below the water surface (~6-inches) and to minimize the burial of the sonde in sediment during decreasing flows and channel meandering. The sonde was retrievable for maintenance and data transfer by pulling up the chain to the bridge deck. Ribbon or flagging was placed every 5-feet on the chain to enhance visibility. The heavy duty chain was attached to the railing by wrapping the chain around the railing and locking the chain to itself at five of the monitoring locations (Louisville, Grand Island, Shelton, Odessa, and Overton). At Kearney, the chain was secured to a steel plate that was attached to unused light pole bolts on the bridge railing.

Flows on the Platte River ranged from low to none (dry) during the monitoring period. No flows or flows too low for water quality monitoring were present at the Duncan and Lexington locations during the monitoring period and sondes were not deployed at these locations. Very low flows resulted in the temporary removal of sondes from the Platte River at Odessa from 2 to 11 October and at Kearney from 3 to 19 September. Sondes were deployed continuously for the monitoring period at Overton, Shelton, Grand Island, and Louisville.

A cracked battery cover on the Kearney sonde resulted in no data collected from 1900 hours on 5 September to 1630 hours on 6 September.

### II.D.2. Continuous Water Quality Sonde Operation and Maintenance

Operation and maintenance was performed weekly on each sonde, including data transfer and calibration (see Table 2 and Table 3). During these visits, hand-held water quality meter measurements, sonde calibration records, and data transfer notes were recorded on the field data sheets.

Directions from the manufacturer for sonde calibration, maintenance, and data transfer were followed. Data was downloaded from the sonde to a field laptop before the data collected exceeded the memory capacity or battery life of the sonde. Files were named by Platte River location as listed in Table 1, followed by month, and day of data transfer (e.g., OVR06SEP). To

ensure file integrity and to provide backup, all files were saved to the laptop hard drive and a portable USB jump drive while in the field. Following the transfer process, files were opened and reviewed to ensure successful transfer of all data before resetting the sonde. While on site, data was reviewed for missing data, outlier data, and logging errors. A field data sheet was filled out for each monitoring location visit to document activities related to sonde maintenance, calibration, setup, and data transfer.

The process for maintenance, data transfer, and calibration of the sondes is outlined below:

- **Measurement Using Hand-Held Meter** – Prior to retrieval of data from the sondes, the field crew collected and recorded duplicate water quality parameters using hand-held water quality meters (YSI-556). A handheld barometric meter was used to collect location and time specific barometric pressure for calibration purposes.

- **Continuous Water Quality Sonde QA/QC** – Duplicate and known (spiked) parameter readings were taken for QC purposes. Duplicate water quality readings were collected by submerging hand-held meter probes in a 5-gallon bucket next to the sonde probes that were set to display real time readings and these values were recorded. Measurements of known (spiked) calibration standards were taken with the sonde during each maintenance visit to assess drift and/or accuracy of the sonde during the monitoring period. These QC measurements were recorded on the field data sheets.

- **Download Data From Continuous Sonde** – The field crew downloaded the data from the sonde to a laptop computer and a portable USB jump drive.

- **Review Continuous Water Quality Data** – After data transfer, data files were opened and reviewed for general data quality (i.e., proper logging interval, abnormal or missing data, data outliers, and missing parameters). If data recording issues were present, the deficiency was documented, the sonde adjusted/fixed, and the corrective action documented.

- **Re-deploy the Sonde** – As a final step, the field crew cleaned and calibrated the sonde following the manufacturer's specification using calibration standards. The documentation of the calibration included the drift of actual reading from the calibrated reading. Once calibrated, the datalogger was turned on and the sonde was re-deployed in the river.

### II.D.3. Hand-Held Water Quality Instrument Operation

As part of Quality Assurance (QA) and Quality Control (QC), a second set of hand-held water quality instruments (capable of reading temperature, dissolved oxygen, pH, specific conductance, and turbidity) were calibrated and maintained to enable the collection of duplicate water quality parameters at the time of site visits. Manufacturer directions for operation, calibration, and maintenance was followed and documented on the field data sheets. These instruments were calibrated at the beginning of each field day prior to monitoring.

The hand-held meter that was used for calibrating specific conductance was designated for checking the accuracy of the water temperature probe. The hand-held meter was checked for accuracy against a mercury-in-glass calibration thermometer that is traceable to the National Institute of Standards and Technology (NIST) certification of its accuracy (Service ID Number 31010C; NIST 1988). A hand-held barometer was also used to collect barometric pressure.

## II.E. Discrete Water Quality Monitoring

### II.E.1. Discrete Water Sample Collection (Metals)

One composite water sample was collected at each monitoring location for laboratory analysis of dissolved copper, dissolved lead, dissolved nickel, total calcium, total magnesium, and total selenium. The following procedures were used to collect representative samples during the discrete sampling events:

- Five grab samples that represented the bulk of the river flow were collected and composited at each monitoring location. The collection points were distributed evenly among multiple river channels or, when one channel existed, samples were taken near each bank and at three equidistant points between banks. When more than five channels existed, the samples were collected from the five channels with the highest flows.

- Before a sample was collected at each site, site water was used to rinse the composite container and stainless steel dip cup at least three times.

- The samples were collected on the upstream side of the bridge.

- A sub-sample was collected at the first station at 1/3 of the water depth using a dip cup. Due to very low to no flow during the monitoring period, the field crew collected samples by wading the river. The sub-sample was poured into the compositing container. Four additional samples were taken at equally spaced representative stations and composited in the composite container.

- Once all predetermined stations were sampled and composited, the composite container was shaken/ swirled to mix the composited sample. Two sample containers were required for each sample. The total metals sample was collected by pouring directly from the composite container into a pre-acidified/pre-labeled sample container. The dissolved metals sample container was filled from the composite container via a peristaltic pump using a new in-line 0.45-µm membrane filter capsule and tubing. Filtrate was discharged directly into the pre-acidified/pre-labeled sample container.

- The sample containers were placed in individual zip-seal bags and stored in a cooler with ice for shipment to the lab.

### II.E.2. Discrete Water Sample Collection (*E. coli*)

*E. coli* samples were collected near the south bank, or from the southern-most channel of the river, to provide sampling consistency. The southern-most channel is the channel that has flowing water and is at least 6-inches deep. A single grab sample of water was collected in a sterilized container (obtained from the laboratory) for *E. coli* analysis at each identified monitoring location. The following procedures were used to collect representative samples for *E. coli* monitoring:

- The sample was collected by wading into the river to the selected sample location. The sampler remained stationary to permit disturbed substrates to be washed away to provide "fresh" water to collect the sample. With the sampler facing upstream the sample was collected in a sterilized container using the following procedure:
    - Hold the sterilized container close to the water surface and remove the lid.
    - Partially submerge the sterilized sample container in the water column.
    - Remove the sample container from the water once it is filled and immediately replace the lid.

- Once the sample was processed, the Chain-of-Custody form was prepared as described in the Water Quality Protocol.

- Samples were hand-delivered to Ward Laboratories, Inc. at 4007 Cherry Ave., Kearney, NE for analysis within 6-hours of collection.

### II.E.3. Analytical Method

The analytical method, required containers, volume, preservative, and holding times are listed in Table 6.

**Table 6. Discrete Sampling Handling and Analytical Methods**

| Analyte | Field Preparation | Method | Container | Holding Time | Method Detection Limit | Reporting Limit | Preservation |
|---|---|---|---|---|---|---|---|
| **Dissolved Metals** | | | | | | | |
| Copper | 0.45 µm filtered water | *SW 7211 | 1000- mL Plastic w/Teflon lined cap | 6 months | 0.0015 mg/L | 0.005 mg/L | Cool, 4ºC $HNO_3$ to pH <2 |
| Lead | 0.45 µm filtered water | *SW 7421 | 1000- mL Plastic w/Teflon lined cap | 6 months | 0.001 mg/L | 0.004 mg/L | Cool, 4ºC $HNO_3$ to pH <2 |
| Nickel | 0.45 µm filtered water | *SW 7521 | 1000- mL Plastic w/Teflon lined cap | 6 months | 0.00435 mg/L | 0.01 mg/L | Cool, 4ºC $HNO_3$ to pH <2 |
| **Total Metals** | | | | | | | |
| Selenium | Un-filtered Water | *SW 7740 | 1000- mL Plastic w/Teflon lined cap | 6 months | 0.00169 mg/L | 0.005 mg/L | Cool, 4ºC $HNO_3$ to pH <2 |
| Calcium | Un-filtered Water | *SW 6010B | 1000- mL Plastic w/Teflon lined cap | 6 months | 0.0195 mg/L | 1.0 mg/L | Cool, 4ºC $HNO_3$ to pH <2 |
| Magnesium | Un-filtered Water | *SW 6010B | 1000- mL Plastic w/Teflon lined cap | 6 months | 0.0104 mg/L | 1.0 mg/L | Cool, 4ºC $HNO_3$ to pH <2 |
| **Bacteria** | | | | | | | |
| *E. coli* | None | **SM 9223C | 100 ml Sterilized Bottle | 6 hours | 1 colony per 100 ml | 1 - 2,419 colonies per 100 ml | Cool, 4ºC |

* SW – Solid Waste
**SM – Standard Methods

*E. coli* samples were analyzed utilizing IDEXX Quanti-Tray following Standard Methods 9223B: Chromogenic Substrate Coliform Test (APHA 1995). *E. coli* counts were determined using Standard Methods 9221C: Estimation of Bacterial Density (APHA 1995).

### II.E.4. Sample Labels

Every sample collected and submitted for analysis had a sample label uniquely identifying the sample and listing the parameters to be analyzed. Each label included the following information:

- Project Name – "PRRIP WQ Monitoring"

- Location Identification – e.g., Lex201204
    - Monitoring locations were identified as follows:
      Lexington – LEX
      Overton – OVR
      Odessa – ODS
      Kearney – KER
      Shelton – SHL
      Grand Island – GRI
      Duncan – DUN
      Louisville – LSV
    - For metals, the location identification was followed by the year and numerical abbreviation for the month sampled. e.g., 201204 – April 2012, 201205 – May 2012.
    - For *E. coli*, the location identification was followed by the day and the abbreviation for the month sampled. e.g., 15MAR – 15 March 2012, 24MAR – 24 March 2012.
- Date of sample collection
- Time of sample collection (military format)
- Analyses to be performed
- Preservative
- Samplers' initials

### II.E.5. QC Sample Collection and Documentation

**Metals**

One duplicate water sample was collected at a randomly selected site during each discrete water quality sampling event. A sufficient volume of water was composited to fill a sample container for the environmental sample and concurrently for the duplicate sample. Duplicate samples were labeled as "Dup" followed by year and month sampled (e.g., DUP201204). An arbitrary sample time was placed on the container label and chain-of-custody. The actual location and sample time were recorded in the field book at the time of sampling.

One field blank was collected during each discrete water quality sampling event. Field blanks were labeled as "FB" followed by year and month sampled (e.g., FB201204). Field blanks were collected using the following procedures:

- The sampling container or Van Dorn bottle was rinsed three times with de-ionized water then rinsed one time with lab-grade water.
- The compositing container was rinsed three times with de-ionized water then rinsed one time with lab-grade water.

- Approximately 1.5 liters of lab-grade water was poured into the sampling container or Van Dorn bottle and then transferred to the composite container. The pre-acidified/pre-labeled total metals sample containers were then filled. For dissolved metals, the field crew drew the lab-grade water from the compositing container through a new filter and tubing into the pre-acidified/pre-labeled sample container.

- The containers were sealed in zip-seal bags and stored in a cooler with ice.

- Field blank samples were processed in the same manner as the environmental samples.

***E. coli***

One field blank was collected for each sampling event for QC using sterile water furnished by the lab to fill the sample container. The sampler filled the field blank container near a point on the river bank where the environmental sample was collected. The sample crew opened both containers simultaneously (sterile water and sample container), filled the sample container with sterile water and immediately replaced the lid. Field blank samples were labeled as "FB" followed by year and month sampled (e.g., FB201203) and handled the same as the environmental samples until delivered to the lab.

### II.E.6. Chain-of-Custody

Every suite of samples collected was tracked and documented via a chain-of-custody record. A chain-of-custody was completed as samples were collected and was submitted with the samples. Each chain-of-custody record included the following:

- Project name – "PRRIP WQ Monitoring"
- Sample identification code – e.g. LEX201204
- Sample date for all samples
- Sample times for all samples (military format)
- Sample type (e.g. composite or grab)
- Required analysis for containers
- Sampler signature for sample collection
- Signature, date, and time relinquished

### II.E.7. Field Book

The following information was documented in the field book or on the field data sheets:

- Date of sampling
- Field crew member names
- Location and sampling beginning and ending times
- Samples collected/work performed in field
- The rationale for choosing each composite location during discrete water sampling
- Duplicates or blanks collected with the location and sampling time
- Weather and site conditions

- Any irregularities encountered and lessons learned during the field effort

### II.E.8. Sample Control and Handling

Sample control and custody is critical to maintain sample integrity for analysis and to track samples from time of collection to time of analysis. The following procedures were followed to maintain sample integrity:

- The sample containers were appropriately labeled and filled with a representative composite or grab water samples.
- The containers were placed in a zip-seal bag in an upright position in a cooler containing ice. The field crew kept the cooler out of direct sunlight and secured in a vehicle to prevent loss of samples/cooler.
- After all samples were collected, the sample containers were cross-checked with the chain-of-custody to ensure required sample information matched.
- Aged ice and water were removed from the cooler and replaced with double-bagged fresh ice along with sample containers and a container labeled temperature blank.
- A completed chain-of-custody was placed in a zip-seal bag and taped to the inside of the cooler lid.
- The field crew placed signed and dated custody seals over the cooler opening prior to sealing with tape.

Once the cooler was sealed with tape, it was delivered to an overnight shipping company for delivery to the laboratory.

## III. DATA SOURCE SUMMARY

The monitoring season for the 2012 water quality monitoring program was initiated 9 August 2012 and completed on 7 December 2012. Water quality was monitored at six of the eight locations (Figure 1) and sondes were co-located near existing USGS or NDNR stage/discharge monitoring locations (gages).

### III.A. Data Collected from USGS

The USGS maintains the National Water Information System (NWIS) website that provides access to water data for locations throughout the United States. EA accessed the USGS website on a monthly basis from August through December to download stage/discharge data from gaging stations located on the Platte River for Louisville, Duncan, Grand Island, Kearney, and Overton. Data that was obtained from USGS is considered provisional data and is subject to revision.

## III.B. Data Collected from NDNR

NDNR collects and reports flow data for streams, canal and pump diversions, and storage in reservoirs at locations throughout Nebraska. The data is gathered through Field Offices and the program is coordinated through NDNR's Planning and Assistance Division. EA utilized information from gaging stations located on the Platte River near Shelton, Odessa, and Lexington. Data that was obtained from NDNR is considered provisional data and is subject to revision.

## III.C. Data Collected by EA

EA installed Hydrolab MS5 and Eureka Manta 2 sondes, and initiated continuous water quality data collection on 9-10 August 2012. Temperature, pH, dissolved oxygen, specific conductance, and turbidity data were collected at 30-minute intervals.

Composite water samples were collected at the eight locations (Figure 1) one time during the monitoring season. Water samples were analyzed for dissolved copper, dissolved lead, dissolved nickel and total selenium, total calcium, and total magnesium.

Grab water samples were collected at the three locations six times during the monitoring season and analyzed for *E. coli* bacteria and coliform bacteria.

As part of the data summarization process it was necessary to determine if water quality data collected was representative of river conditions. The field data sheets were reviewed to identify variables which may have affected data quality. Several of the field sheets described conditions that may have affected the sondes ability to collect representative water quality data. Issues which affected water quality data and were evident in the water quality values logged included:

- The measurement cell on the specific conductance probes were filling with sediments at the electrodes, even in high velocity areas of the river. This decreased the functionality of the probe resulting in depressed specific conductance readings.
- Algal growth occluded the optical lenses on the turbidity and dissolved oxygen probes, resulting in elevated turbidity and erratic dissolved oxygen readings.
- Aquatic insects of the Order Trichoptera colonized on the probes affecting pH, specific conductance, dissolved oxygen, and turbidity.
- Parameter specific probes on the sondes would malfunction or fail resulting in no data being collected.

Further discussions on the variables affecting water quality data are presented in Section III.D and Appendix C.

## III.D. Data Quality Control Summary

The Quality Control Summary describes the results of the data quality evaluation performed on the water quality parameters collected during the 2012 monitoring season. Data quality for the 2009, 2010, and 2011 baseline water quality monitoring years is evaluated in their respective

"Annual Data Summary Reports" (PRRIP 2010, 2011, and 2012). Data collected in 2012 included: temperature, specific conductance, pH, turbidity, dissolved oxygen, and discharge. Analytical data collected included: dissolved copper, dissolved lead, dissolved nickel, total selenium, total calcium, total magnesium, and E. coli. Overall the quality of the Platte River water quality data collected was found to be of sufficient quality to characterize the water quality during the monitoring period. The quality of the data collected and analyzed was assessed using the elements of precision, accuracy, representativeness, completeness, and comparability. Results of the Data Quality Control Summary are presented in Appendix C.

## IV. DATA SUMMARY

Summary statistics were completed after the data had been reviewed to ensure the data summarized were representative of water quality in the central and lower Platte River. The 2012 action-based water quality summary statistics were calculated for the index period of 9 August to 7 December which is inclusive of the Platte River Program actions implemented from 21 August 2012 to 30 November 2012. Baseline Platte River water quality was summarized for 2009, 2010, and 2011 from 9 August to termination of data collection for the respective years. All data was loaded into Microsoft® Access 2010 database for manipulation of the data and summarized and/or statistical analyses performed using R statistical software (http://www.r-project.org/) or Microsoft® Excel 2010. Summarization included a tabular presentation of weekly observations (number (N), mean, maximum, minimum, and standard deviation) for each parameter. Data was graphed to present observed temporal and spatial variations. Index period summary statistics for 2009, 2010, 2011, and 2012 are presented in Appendix A. Raw water quality data from the 2012 monitoring year and flow data are presented on a CD referenced in Appendix F and G, respectively. Raw water quality and flow data are presented in the respective monitoring years: "Annual Data Summary Report" (PRRIP 2010, 2012c, and 2012d).

### IV.A. 2012 Variations (intra-year)

Variations in the 2012 water quality data (weekly means) were evaluated after raw data had been reviewed to ensure that the data was representative of water quality in the central and lower Platte River. Data was assessed for temporal and spatial variations in context to Platte River Program actions.

#### IV.A.1. Temporal Variation

Temporal variation of water quality parameters were assessed using line graphs showing all monitoring locations (i.e., X-axis presents time, Y-axis presents parameter value) and are presented in Appendix B, Figures B-1 through B-6. The very low to no discharge at Lexington and Duncan prevented the deployment of the water quality data sondes and no water quality data was collected in 2012.

- **Temperature –** Water temperature exhibited the same seasonal temporal trend at the six locations during the monitoring season. Water temperatures trended downward from the initially observed late summer temperatures to the minimum observed temperatures observed in early December. Platte River water temperature displayed no evidence of temporal variation as a result of Program-actions in the central Platte River.

- **Specific Conductance –** Specific conductance exhibited no temporal trend at the five of the six locations during the monitoring season. The weekly mean of specific conductance remained stable during the monitoring season at five of the six monitoring locations, and weekly means consistently ranged between 0.740 and 0.910 mS/cm (delta=0.170). The data sonde at the Louisville monitoring location was initially deployed at the south end of the Platte River Bridge from 12 September to 10 October. On 10 October the sonde was moved and redeployed from the north end of the bridge until the end of the monitoring period on 7 December. The specific conductivity of the Platte River is demonstrably different between the north and south sides of the wetted channels. On the south side of the River the specific conductivity mean was 1.128 mS/cm from 12 September to 10 October. On the north side of the River the specific conductivity mean was 0.494 mS/cm from 10 October to 7 December. This temporal variation in specific conductance at the Louisville monitoring location is not a product of Program actions, but is the result of sonde placement on the bridge and is a function of tributary water "sourced" from Salt Creek on the south side/channel of the Platte River and consequently the sonde located at the Bridge.

- **pH –** pH concentrations at the six monitoring locations consistently ranged between 7.5 and 9.0 pH. Temporal trends were not evident in the data during the monitoring season. pH displayed no evidence of temporal variation as a result of Program-actions in the central Platte River. Difference in the sonde deployment location at the Louisville monitoring location during the monitoring period is also evident in the pH data. Initial weekly mean pH ranged from 8.6 to 9.0 and decreased to a weekly mean ranging from 8.3 to 8.4 after the sonde was moved.

- **Turbidity –** Turbidity exhibited the same temporal trend at three of the six locations during the monitoring season; Overton, Shelton, and Grand Island. Turbidity at Louisville exhibited a temporal trend independent of the other five locations with higher turbidity concentrations. Odessa and Kearney displayed turbidity concentrations similar to that observed at Overton, Shelton, and Grand Island from 6 August until 17 October. The 24 October weekly mean for turbidity showed a marked increase at Odessa and Kearney that was not evident in the Overton, Shelton, and Kearney turbidity weekly means. The elevated turbidity trend at the Odessa and Kearney monitoring locations was evident in the data from 24 October through termination of monitoring activities. The apparent temporal turbidity variation is discussed further in Section V.

- **Dissolved Oxygen –** Dissolved Oxygen exhibited the same temporal trend at the six locations during the monitoring period. Weekly mean concentrations of dissolved oxygen in the water were lowest during the summer months when water temperatures are higher and highest during the cold water periods observed at the end of the monitoring period. This follows the inverse relationship that as temperature increases the solubility of gas in water decreases. Dissolved oxygen displayed no evidence of temporal variation as a result of Program-actions in the central Platte River.

- **Discharge –** Weekly mean discharge (cfs) was collected at the eight monitoring locations. Discharge at Louisville exhibited a temporal trend that was different than the other seven monitoring locations. Weekly mean discharge consistently increased at Louisville and did not plateau until 14 November. Weekly mean discharge at the seven monitoring locations remained consistent throughout the monitoring period. Discharge displayed no evidence of temporal variation as a result of Program-actions in the central Platte River.

### IV.A.2. Spatial Variation

Intra-year spatial variation was assessed using boxplots of the water quality parameters values for all monitoring locations (i.e., X-axis presents monitoring location, Y-axis presents parameter value). Box plots present minimum, 25$^{th}$ percentile, median, 75$^{th}$ percentile, and maximum values of the parameter. Boxplot figures for each water quality parameter monitored are presented in Appendix B, Figures B-7 through B-14.

- **Temperature –** No spatial variation was evident in the boxplots by monitoring location presenting water temperature at the six monitoring locations. Temperature ranges (minimum and maximum) observed at the eight locations were essentially the same for the monitoring period. Temperature displayed no evidence of spatial variation as a result of Program-actions in the central Platte River.

- **Specific Conductance –** Spatial variation was evident in the boxplots by monitoring location presenting specific conductance for the monitoring season. Specific conductance exhibited two groupings of data for the monitoring period. The Louisville monitoring locations exhibited a large maximum (1.630 mS/cm) to minimum (0.250 mS/cm) range up to two times greater than the other five monitoring locations. Overton, Odessa, Kearney, Shelton, and Grand Island monitoring locations had similar specific conductance levels. The Louisville monitoring location high specific conductance range is the result of sonde placement on the bridge and is discussed in further in Section IV.A.1. Specific Conductance displayed no evidence of spatial variation as a result of Program-actions in the central Platte River.

- **pH –** No spatial variation was evident in the boxplots by monitoring location presenting pH at the six monitoring locations. The mid-value (25$^{th}$ to 75$^{th}$ percentile range) pH was essentially the same for the monitoring period at the six locations. The minimum observed pH at Kearney was 1 Standard pH Unit lower than minimum pH observed at the five other monitoring locations. The demonstrably lower pH at Kearney is evident on the temporal variation graph (Figure B-3). The low pH observed at Kearney relative to the other monitoring locations was also observed in the 2011 baseline data (Figure B-17).

- **Turbidity –** Spatial variation was evident in the boxplots by monitoring location presenting turbidity for the monitoring season. Turbidity at the Louisville monitoring location was higher than Grand Island, Shelton, Kearney, Odessa, and Overton monitoring locations. Turbidity was similar at the Grand Island, Shelton, Odessa, and Overton monitoring locations. The observed turbidity range at Louisville was

significantly higher than what was observed at the other five monitoring locations. The 25th to 75th percentile turbidity range at the Kearney location was noticeably different than the other five monitoring locations (log-turbidity Figure B-11).

The 2012 turbidity data was refined further to evaluate Program-actions on Platte River water quality by calculating boxplot parameters on a weekly basis for the duration of the project. Figure B-12 presents weekly spatial variation by location during the 2012 Platte River water quality monitoring period 9 August to 6 December 2012. Evident in the weekly boxplot data is a weekly mean peak at the Odessa and Kearney for the week of 24 October that is not evident at the Overton and Shelton monitoring locations. The Odessa and Kearney observed elevated turbidity is discussed in further detail in Section V.

- **Dissolved Oxygen –** No spatial variation was evident in the boxplots presenting dissolved oxygen at the six locations monitored. Dissolved oxygen values at the 25th to 75th percentile range were similar. Dissolved oxygen displayed no evidence of spatial variation as a result of Program-actions in the central Platte River.

- **Discharge –** Spatial variation was evident in the boxplots by monitoring location presenting discharge (cfs) for the monitoring season. Discharge at the Louisville monitoring location (downstream of other monitoring locations) is discernibly higher than the other monitoring locations. No discharge (dry) was recorded by the USGS at the Duncan location from 6 August until first recordable flow was observed on 12 September and at the Grand Island location had no flow recorded from 6 August until 26 August. Shelton, Kearney, Odessa, Overton, and Lexington had recordable flows throughout the monitoring period. However, depth of flow at Duncan and Lexington were not sufficient for deployment of the water quality data sonde. Discharge displayed no evidence of spatial variation as a result of Program-actions in the central Platte River.

### IV.A.3. Metals

One discrete sampling event was performed for the collection of composite water samples for the analyses of total and dissolved metals during the 2012 water quality monitoring season. Samples were collected on 27 October 2012 at the eight water quality monitoring locations. Samples were analyzed for total calcium, magnesium, selenium and dissolved copper, lead, and nickel. Dissolved copper, lead, nickel, and total selenium were reported as non-detect or less than the laboratory reporting limit in the eight environmental samples submitted for analysis. Total calcium and magnesium were reported in all eight samples submitted for analysis (Appendix A, Tables A-39).

Table A-40 (Appendix A) presents the number of samples, min, max, detected number and reported means for metal samples analyzed in 2009, 2010, 2011, and 2012. The October 2012 reported minimum and maximum calcium and magnesium concentrations where within the observed historical range. Dissolved metals copper, lead, nickel and total selenium where non-detect in 2012 which is consistent with the historical data. The reported calcium and magnesium in the Platte River are consistent with concentrations reported for the three base-line years.

### IV.A.4. Bacteria

Six discrete sampling events at three locations were performed for the collection of water samples for analysis of coliform and *E. coli* bacteria during 2012. Results of the bacteria analysis are presented in Appendix A, Table A-42. A total of 18 samples were collected for coliform and *E. coli* analysis and colonies for the respective bacteria were reported in all the samples collected. Coliform bacteria exhibited higher colony numbers in September than in March with the exception of a March 7 peak at Grand Island and a March 14 peak at Kearney (3 samples in March and 3 in September: Appendix B, B-28). Field notes for the sample dates indicated a high concentration of sandhill cranes on the Platte River upstream of the Grand Island and Kearney sampling location. It is unknown what the cause of the high coliform counts is in September.

*E. coli* Colonies per 100ml of sample water at Grand Island ranged from a 7 March high of 3,784 colonies to a 5 September low of 35 colonies/100ml (Appendix B, B-29). At the Lexington, E. coli concentrations peaked on 20 September (172 colonies) and in Kearney the peak was 5 September (488 colonies).

## IV.B. Baseline Years variation (inter-year)

The 2012 water quality data (daily means) *collected* during Program-actions on the central Platte River is compared to the "baseline" water quality data collected in 2009, 2010, and 2011 (inter-year). Inter-year variations were assessed for temporal and spatial variations due to Program actions during the 2012 index period of 9 August to termination of data collection for each of the four respective water quality monitoring years.

### IV.B.1. Temporal Variation

Inter-year temporal variation of water quality parameters were assessed using line graphs showing the three baseline years (2009, 2010, and 2011) and the Program-action year (2012) by monitoring locations (i.e., X-axis presents time, Y-axis presents parameter value) and are presented in Appendix B, Figures B-15 through B-20. Deployment of the data sondes at Lexington and Duncan was not completed in 2012 due to very low to no discharge. No water quality data was collected at these two monitoring locations in 2012.

- **Temperature** – Inter-year water temperature exhibited the same trend at the monitoring locations. Water temperature decreased from summer highs to low temperatures expected during late fall. Of note in this series of graphs is the increased range of daily mean water temperature fluctuations evident in 2012 from 5 October to the termination of data collection. This trend is evident at all of the monitoring locations and is not reflective of Program-actions. This fluctuation is more of a product of the very low flows in the Platte River in 2012 (Figure B-20) which represents a smaller volume of water in the river that is more susceptible to daily water temperature extremes.

- **Specific Conductance** – Inter-year specific conductance exhibited similar trends and similar data ranges for the four observations years at the eight monitoring locations. The

2012 specific conductance at Louisville was not similar to specific conductance observed in 2009, 2010, and 2011. The 2012 specific conductance variation at the Louisville monitoring location is discussed in further detail in Section IV.A.1.

- **pH** – Inter-year pH concentrations exhibited similar trends and similar data ranges for the four observation years at the eight monitoring locations. The 2012 pH concentrations at all monitoring locations were within the pH ranges observed in 2009, 2010, and 2011.

- **Turbidity** – Inter-year 2012 daily mean turbidity concentrations was markedly lower at Overton, Odessa, Kearney Shelton, and Grand Island monitoring locations than turbidity observed during the baseline years (2009, 2010, and 2011). Daily mean 2012 turbidity concentration at the Louisville monitoring location was within the range of turbidity concentrations observed during the baseline years. The low turbidity concentrations observed in 2012 are a product of very low river flows -- a result of no precipitation events in the Platte River basin due to the drought conditions in 2012. Conversely, turbidity concentrations that were higher than the baseline years were evident at Odessa and Kearney monitoring locations from approximately 20 October to the termination of the study. This increase in turbidity concentration is discussed in further detail in Section V.

- **Dissolved Oxygen** – Inter-year dissolved oxygen exhibited similar data ranges for the four observation years at the eight monitoring locations. The 2012 dissolved oxygen concentrations at all monitoring locations exhibited similar dissolved oxygen trends to those observed in 2009, 2010, and 2011.

- **Discharge** – Inter-year discharge was not similar for the four observation years at the eight monitoring locations. Discharge is an independent variable from Platte River water quality and different yearly discharge regimes were observed at the eight monitoring locations. The 2012 discharge regime at all locations was consistently lower than it was during the three baseline years (2009, 2010, and 2011). The effects of the low discharge regime in 2012 are discussed further in Section V.

### IV.B.2. Spatial Variation

Inter-year spatial variation was assessed using boxplots of the water quality parameters values for all monitoring locations (i.e., X-axis presents monitoring location, Y-axis presents parameter value). Box plots present Platte River water quality data collected in 2009, 2010, 2011, and 2012 for the 2012 monitoring period of 9 August to 6 December by monitoring location. Box plots present minimum, 25th percentile, median, 75th percentile, and maximum values of the parameter. Boxplot figures for each water quality parameter monitored are presented in Appendix B, Figures B-21 through B-26.

- **Temperature** – No spatial variation in water temperature was evident in the boxplots presenting monthly data by location at the eight monitoring locations. Temperature ranges (minimum and maximum) observed at the eight locations were essentially the same for the baseline years and the Program-action monitoring period. Temperature

displayed no evidence of inter-year spatial variation as a result of Program-actions in the central Platte River.

- **Specific Conductance** – Spatial variation was evident in the boxplots presenting monthly data by location at the eight monitoring locations. The 2012 specific conductance displayed a wider range of data (minimum to maximum) at Overton, Odessa, Kearney, and Shelton than what was seen for the baseline years. The Louisville September 2012 boxplot is demonstrable different than the baseline years and the 2012 data. The Louisville monitoring location high specific conductance range is the result of sonde placement on the bridge and is discussed in further in Section IV.A.1. Specific Conductance displayed no evidence of inter-year spatial variation as a result of Program-actions in the central Platte River.

- **pH** – No spatial variation in pH was evident in the boxplots presenting monthly data by location at the eight monitoring locations. pH ranges (minimum and maximum) observed at the eight locations were essentially the same for the baseline years and the Program-action monitoring period. pH displayed no evidence of inter-year spatial variation as a result of Program-actions in the central Platte River.

- **Turbidity** – Turbidity variation was evident in the boxplots presenting monthly data by location at the eight monitoring locations (log turbidity; Appendix B, Figure B-24). The 2012 turbidity by month and monitoring location at Overton, Odessa, Kearny, Shelton, and Grand island had a much wider minimum to maximum range as well as the 25$^{th}$ to 75$^{th}$ percentile range than the baseline years. This increased boxplot range was not evident in the Louisville turbidity data. The turbidity data range increase is discussed further in Section V.

- **Dissolved Oxygen** – No spatial variation was evident in the boxplots presenting monthly data by location at the eight monitoring locations. Dissolved oxygen ranges (minimum to maximum) observed at the eight locations was essentially the same and exhibited the same trend of increasing DO as water temperatures decreased. Dissolved oxygen displayed no evidence of inter-year spatial variation as a result of Program-actions in the central Platte River.

- **Discharge** – Discharge variation was evident in the boxplots presenting monthly data by monitoring location at the eight monitoring locations (log discharge; Appendix B, Figure B-26). Discharge at the Louisville monitoring location (downstream of other monitoring locations) was demonstrably lower in 2012 when compared to the baseline years. Discharge at Overton, Odessa, Kearney, Shelton, Grand Island, and Duncan (when present) were demonstrable lower than the baseline years and more variable with higher minimum to maximum range than the baseline years too. The wide range in discharge at the list locations with the exception of Duncan and Lexington is a product of hydropower cycling by Central Nebraska Public Power and Irrigation district where water via the J-2 Return is discharge to the Platte River. The effect of hydro-cycling on Platte River discharge is discussed in more detail in Section V.C. Discharge at the Lexington

monitoring location was demonstrable less than the baseline years and had a minimum to maximum range that is comparable to baseline discharge data ranges.

## V. STATISTICAL EVALUATION OF 2012 TURBIDITY

Box plots and time series graphs of the daily and weekly averaged turbidity observations suggest that there may be an increase in turbidity around the week of October 20 at the Odessa and Kearney locations in 2012 (Figures B-4, B-11, B-12, B-18, and B-24). We evaluated this possible change relative to the baseline (2009-2011) and the 2012 turbidity data using statistical methods:

- A Student's t-test was used to evaluate whether the mean of the observed turbidity is different between two time periods: (A) 6 August – 20 October and (B) 21 October -7 December. We applied this test at each water quality station in 2010, 2011, and 2012. The baseline year 2009 was excluded because data collection in that year ended in early October.
- A series of linear regression models were fit to the Platte River discharge and turbidity data to evaluate if a change in discharge is the reason for the observed increase in turbidity at Odessa and Kearney.
- A series of linear regression models were fit to the J-2 return discharge and turbidity to evaluate if the J-2 discharge is the reason for the observed increase in turbidity at Odessa and Kearney.

### V.A. Student's t-test

Table 7 summarizes test results. The column labeled "p-value" indicates the probability that the observed difference between the two means is not significant. Commonly, p-values are compared to a pre-determined probability (i.e., 0.05 which corresponds to a 95% confidence value) to decide whether to reject a null hypothesis in favor of an alternative hypothesis. In this case, the null hypothesis is that there is no difference in turbidity between period A and period B at each location and year. As summarized in the last column, in almost every case, the null hypothesis is rejected in favor of the finding that the turbidity is lower in Period B than Period A. That tells us that, in general, turbidity tends to decrease from August to December in the Platte River. However, for the two data sets in bold (Odessa 2012 and Kearney 2012), there is a significant increase in turbidity between the two time periods, meaning that average turbidity is actually higher from 21October -7 December than it is 6 August- 20 October in 2012.

**Table 7. Student's t-test Results Comparing Turbidity Before and After October 20 Each Year**

| Location | Years | Mean Turbidity (NTU) | | | p-value | Significant change? |
|---|---|---|---|---|---|---|
| | | Period | | | | |
| | | (A) Aug 6-Oct 20 | (B) Oct 21-Dec 7 | Difference (A-B) | | |
| Lexington | 2010 | 15.5 | 13.9 | 1.6 | 0.14 | no |
| | 2011 | 28.9 | 10.9 | 18.0 | <0.001 | decrease |
| | 2012 | -- | -- | -- | -- | -- |
| Overton | 2010 | 18.7 | 14.4 | 4.2 | 0.001 | decrease |
| | 2011 | 39.0 | 19.6 | 19.4 | <0.001 | decrease |
| | 2012 | 17.6 | 9.4 | 8.2 | <0.001 | decrease |
| Odessa | 2010 | 42.8 | 32.8 | 10.0 | 0.001 | decrease |
| | 2011 | 52.4 | 17.0 | 35.4 | <0.001 | decrease |
| | **2012** | **14.8** | **32.3** | **-17.5** | **0.001** | **increase** |
| Kearney | 2010 | 41.9 | 23.6 | 18.3 | <0.001 | decrease |
| | 2011 | 46.7 | 18.5 | 28.3 | <0.001 | decrease |
| | **2012** | **8.7** | **18.7** | **-10.1** | **0.003** | **increase** |
| Shelton | 2010 | 69.4 | 34.3 | 35.1 | <0.001 | decrease |

## V.B. Discharge/Turbidity Linear Regression Model

Turbidity can be affected by river discharge, and to evaluate whether a change in discharge is the reason for the observed increase in turbidity at Odessa and Kearney, a series of linear regression models were fit to the turbidity data. Because of the variable nature of the river discharge in the fall of 2012 (Figure B-6) we used weekly average observations for the regression models to reduce autocorrelation in the data sets. The regression model fit to the August-December observations for both the baseline (2009-2011) and 2012 datasets at each station is:

$$\text{Turbidity} = \beta_0 + \beta_1(\text{week}) + \beta_2(\text{flow})$$

This model tests for a relationship between turbidity and flow, as well as for a trend in turbidity over time. Both flow and turbidity were log-transformed to normalize the values for use in a linear regression model.

Regression model results are presented in Table 8. For each variable, the slope indicates whether the relationship between the variable and turbidity is positive or negative, and the p-value indicates the significance of the relationship. If the p-value is less than 0.05, we can say that the variable is significantly related to turbidity at the 95% confidence level. As expected, the results show that turbidity and flow are significantly positively related in most cases (e.g., when flow is higher, turbidity is higher). In addition, when we examine the slope on the temporal parameter (week) for the baseline data sets, we can say that after accounting for flow effects, the turbidity decreases from August to December during the baseline period. Likewise, in 2012 at Overton turbidity is also decreasing over time after accounting for flow. However, in 2012 at Odessa and Kearney, even after accounting for flow, the turbidity is not decreasing over time. The results at Shelton, Grand Island, and Louisville are more variable, leading us to the conclusion that the turbidity variations on the river are occurring primarily upstream of the Odessa and Kearney locations.

**Table 8. Regression model fit for weekly average turbidity from August to December using the model: $\log(\text{Turbidity}) = \beta_0 + \beta_1 \text{ week} + \beta_2(\log(\text{flow}))$**

## V.C. J-2 Discharge/Turbidity Linear Regression Model

A series of linear regression models were developed to evaluate the effect of the J-2 Return discharge on the turbidity in the Platte River. In each case, a simple linear regression model was fit between observed daily turbidity at the water quality observation location and the discharge observed at the J-2 Return. Figure B-29 presents the 2012 J-2 discharge returned to the Platte River and Platte River discharge at Overton, NE from August to December 2009 to 2012. Platte River discharge at Overton in 2012 is a product of the J-2 discharge to the river and the J-2 return is located upstream of the Program-actions completed in 2012.

Results of this regression analysis (Table 9) demonstrate a significant relationship between turbidity and the J-2 Return flow at the four locations examined (Overton, Odessa, Kearney, and Shelton). The residuals from these regressions were plotted (Figures B-30 to B-33). For a more representative regression of J-2 discharge on turbidity the travel time from J-2 to the Kearney and Shelton monitoring locations was taken into account by pairing the observed turbidity (daily) with the previous day (24-hours earlier) J-2 discharge. Examining the regression residuals over time reveals if there are any underlying patterns in turbidity after removing the influence of the discharge at the J-2 Return. If the J-2 discharge explains most of the variability in the turbidity, we expect to see a random distribution of residuals above and below zero throughout the time series. Instead, we see a variety of patterns in the regression residuals at the four locations examined. At Overton, the turbidity-flow residuals decrease over time, which is consistent with the decreasing trend in turbidity that we saw in the baseline years for the August to December time period (Figure B-18). However, a residual peak was evident at Overton around 27 August that is not explained by discharge and occurred prior to the time Program-actions were performed. At Odessa and Kearney, on the other hand, we see some large peaks in the residuals after mid-October. This means that the cycling of the flow at the J-2 Return does not explain all of the variability in the turbidity at these two locations in October and November 2012. The regression residuals at Shelton follow a more random pattern throughout the entire time period, perhaps with a slight decreasing trend as expected from the baseline turbidity data during this period.

**Table 9. Regression model fit for 2012 daily average turbidity from August to December using the model: Turbidity = $\beta_0 + \beta_1$ (J-2 flow)**

| Location | $R^2$ | Flow | |
|---|---|---|---|
| | | slope | p-value |
| Overton | 0.46 | 0.015 | <0.001 |
| Odessa | 0.37 | 0.019 | <0.001 |
| Kearney* | 0.65 | 0.023 | <0.001 |
| Shelton* | 0.51 | 0.015 | <0.001 |

*Note: Model was fit between daily turbidity and the previous day's flow observed at the discharge Return because of the time required for flow down the river.

# VI. SUMMARY

Platte River water quality monitoring was performed to monitor water quality of the central and lower Platte River during one minor (island building) and two major (sediment augmentation at the Dyer property and Cottonwood Ranch) Program actions in 2012. The inclusive water quality monitoring period was from 21 August to 7 December 2012. Water quality data was collected at Overton, Odessa, Kearney, Shelton, Grand Island, and Louisville monitoring locations. Because of very low flow and/or no flow conditions at Lexington and Duncan no water quality data was collected. Platte River water quality data was summarized and studied to determine if Program-actions altered intra-year water quality (upstream v. downstream) and inter-year water quality (2009, 2010, and 2011 baseline years v. 2012).

No monitored water quality changes were noted in the inter- and intra-year data evaluation as a result of the island building (minor event) Program-action performed in 2012 (Figure B-34). A turbidity peak is evident at the Overton monitoring location during the island building time period. The spike in turbidity is not a product of Program action since the Overton monitoring location is located upstream of the Program island building action that was completed in 2012.

Evidence of the Program's sediment augmentation (major events) effect on Platte River water quality was evident in the inter- and intra-year turbidity data. The Program completed two major sediment augmentation events in the central Platte River in 2012 (Table A-43 and Table A-44).

- Sediment Augmentation – Dyer Property. Action performed from 26 September 2012 through 30 November 2012 upstream of the Overton monitoring location. Augmentation material was produced by establishing a sand pit operation at an existing sand pit at the Dyer property. The sand pumping operation produced augmentation material that was pumped to an active river channel for disbursement.
- Sediment Augmentation – Cottonwood Ranch. Action performed from 17 September 2012 through 30 November 2012 upstream of the Odessa monitoring location. Augmentation material was produced by mechanical placement of existing material located in high areas within the river channel into active flowing areas within the Platte River channel.

The discharge point for the sand pumping operation was located approximately 1 mile upstream of the Overton monitoring location. Figure B-35 presents turbidity, Platte River discharge at the Overton, Odessa, and Kearney monitoring locations, and sediment augmentation discharge periods into the Platte River. Turbidity at the Overton location did not increase as a result of the sand pumping operation for sediment augmentation. Statistically, turbidity at Overton in 2012 was not significantly different ($p=0.05$) between the pre- and active augmentation time periods and between turbidity in 2012 and turbidity in the baseline years. Linear regression models for flow and turbidity were significantly positive at the 95% confidence interval accounting for all of the observed turbidity at Overton during the study period. Statistically there is no evidence that the sand pumping operation for sediment augmentation of the Platte River affected the water quality observed at the Overton monitoring location.

The area for sediment augmentation by mechanical placement of sediments into a Platte River channel was located approximately 5 miles upstream of the Odessa monitoring location (approximately 3.5 miles downstream of Overton – Figure 2). Figure B-36 presents turbidity, Platte River discharge at Overton, Odessa, and Kearney monitoring locations and sediment augmentation periods into the Platte River. Peaks in turbidity are evident at Odessa and Kearney that are significantly different (P>0.05) between the turbidity prior to sediment augmentation, within the active augmentation time period, and between 2012 turbidities and the baseline year turbidities. Linear regression models for flow and turbidity at Odessa and Kearney were not significant indicating that flow could not account for all of the observed turbidity. Additionally, residuals from the flow and turbidity linear regressions models that account for turbidity induced by flow do not explain all of the observed turbidity at Odessa and Kearney. Statistically there is evidence that Program-actions, specifically sediment augmentation via mechanical placement of sediments increased ambient turbidity levels in the Platte River.

# I. QUALITY CONTROL SUMMARY

The Quality Control Summary describes the results of the data quality evaluation performed on the water quality parameters collected during the 2012 monitoring season. Data collected in 2012 included: temperature, specific conductance, pH, turbidity, dissolved oxygen, and discharge. Analytical data collected included: dissolved copper, dissolved lead, dissolved nickel, total selenium, total calcium, total magnesium, and *E. coli*. Overall the quality of the Platte River water quality data collected was found to be of sufficient quality to characterize the water quality during the monitoring period. The quality of the data collected and analyzed was assessed using the elements of precision, accuracy, representativeness, completeness, and comparability.

## I.A. Precision

The measurement of precision was accomplished by collecting duplicate water quality readings and duplicate samples. The premise being that two samples collected simultaneously from the same location should yield similar results. The variation between duplicate samples that is accepted is a function of the monitoring objectives and the inherent variation around each parameter. Precision was measured during the Protocol in terms of Relative Percent Difference (RPD) which is calculated using the following formula:

$$RPD = (X_1-X_2)/[(X_1+X_2)/2]$$

$X_1$ and $X_2$ = reported concentrations for each duplicate sample.

Data was considered in agreement if the RPD was less than or equal to 50% for each parameter.

### I.A.1. Continuous Water Quality Data

Duplicate water quality readings were collected for continuous water quality data using hand-held meters for temperature, specific conductance, pH, turbidity, and dissolved oxygen at each location during each sonde maintenance event. A summary of duplicate readings that exceeded the 50% RPD threshold is presented in Table 1 and all duplicate sample collection results are presented in Appendix C, Table C-2 through C-7.

**Table C-1. Relative Percent Difference (RPD) Exceedance for Duplicate Samples**

| Parameter | Location | Date | Hand Held | Sonde | RPD |
|---|---|---|---|---|---|
| Turbidity | Louisville | 23 October 2012 | 14.00 | 57.20 | 121.35% |
| Turbidity | Louisville | 6 November 2012 | 25.40 | 42.90 | 51.24% |
| Turbidity | Grand Island | 1 October 2012 | 6.72 | 4.00 | 50.75% |
| Turbidity | Shelton | 17 August 2012 | 9.21 | 15.50 | 50.91% |
| Turbidity | Shelton | 6 September 2012 | 20.70 | 48.20 | 79.83% |
| Turbidity | Shelton | 13 September 2012 | 10.21 | 5.20 | 65.02% |
| Turbidity | Shelton | 24 October 2012 | 2.24 | 0.00 | 200.00% |
| Turbidity | Shelton | 1 November 2012 | 2.34 | 1.10 | 72.09% |
| Turbidity | Shelton | 6 November 2012 | 2.03 | 1.20 | 51.39% |
| Turbidity | Shelton | 20 November 2012 | 3.48 | 1.40 | 85.25% |
| Turbidity | Kearney | 23 August 2012 | 5.29 | 2.50 | 71.63% |
| Turbidity | Kearney | 13 September 2012 | 0.82 | 0.00 | 200.00% |
| Turbidity | Kearney | 26 September 2012 | 0.40 | 0.00 | 200.00% |
| Turbidity | Kearney | 24 October 2012 | 0.52 | 0.00 | 200.00% |
| Turbidity | Kearney | 2 November 2012 | 2.02 | 0.80 | 86.52% |
| Turbidity | Kearney | 20 November 2012 | 2.10 | 0.00 | 200.00% |
| Turbidity | Kearney | 29 November 2012 | 6.85 | 3.00 | 78.17% |
| Turbidity | Odessa | 13 September 2012 | 1.86 | 0.00 | 200.00% |
| Turbidity | Odessa | 6 November 2012 | 21.60 | 42.50 | 65.21% |
| Turbidity | Overton | 13 September 2012 | 2.36 | 1.00 | 80.95% |
| Turbidity | Overton | 19 September 2012 | 3.60 | 1.30 | 93.88% |
| Turbidity | Overton | 26 September 2012 | 3.52 | 0.40 | 159.18% |
| Turbidity | Overton | 21 November 2012 | 4.72 | 1.90 | 85.20% |
| Turbidity | Overton | 30 November 2012 | 3.17 | 0.30 | 165.42% |

N/A = Not Applicable

The procedure for collecting duplicate water samples was to retrieve the sonde from the river and immediately place it in a five gallon bucket of Platte River water in the shade. The handheld instruments used for the paired readings were than immersed in the same bucket with the sonde and permitted to equilibrate. During the equilibration period, the sonde was connected to the laptop and set to display live readings of the water quality parameters being measured. Once the parameters stabilized, readings were recorded on the field data sheets.

- **Temperature** – All of the possible 86 duplicate readings were taken for temperature during the 2012 monitoring season. None of the paired readings exceeded the 50% RPD for duplicate temperature readings. The minimum RPD was 0.00%, and the maximum RPD was 19.00%.

- **Specific Conductance** – All of the possible 86 duplicate readings were taken for specific conductance during the 2012 monitoring season. None of the paired readings exceeded the 50% RPD with a minimum RPD of 0.00% and maximum RPD of 3.54%.

- **pH** – All of the possible 86 duplicate readings, were taken for pH during the 2012 monitoring season. None of the paired readings exceeded the 50% RPD for duplicate pH readings with a minimum RPD of 0.00% and maximum RPD of 12.28%.

- **Turbidity** – All of the possible 86 duplicate readings were taken for turbidity during the 2012 monitoring season. Of the paired RPD readings, 24 exceeded the 50% RPD for duplicate turbidity readings ranging from 50.75% to 200.00%. The minimum RPD for turbidity was 0.00%. High RPD readings for turbidity resulted from biological fouling, algal growth and insect colonization on the optical lens of the turbidity probe.

- **Dissolved Oxygen** – All of the possible 86 duplicate readings were taken for dissolved oxygen during the 2012 monitoring season. None of the paired readings exceeded the 50% RPD for duplicate dissolved oxygen readings with a minimum RPD of 0.08% and a maximum RPD of 18.66%.

### I.A.2. Discrete Water Quality Data

One duplicate water sample was collected for each discrete water sampling event. A summary of duplicate readings is described below and all duplicate sample collection results are presented in Appendix C, Table C-14 through C-20.

- **Metals** – One water sampling event was performed during the 2012 monitoring season for the collection and analysis of metals. Water samples were analyzed for dissolved copper, dissolved lead, dissolved nickel, total selenium, total calcium, and total magnesium. A duplicate water sample was collected during the sampling event for precision analysis. RPD for the metal analysis were all less than 50%, ranging from a minimum of 0.87% to a maximum of 1.72%.

- ***E. coli*** – Six water sampling events were performed during the 2012 monitoring season for the collection and analysis of bacteria. Water samples were analyzed for coliform bacteria and *E. coli* bacteria. A duplicate water sample was collected during each sampling event for precision analysis. Two samples exceeded 50% RPD for the *E. coli* analysis and ranged from a minimum of 0.00% to a maximum of 185.27%. Four samples exceeded the 50% RPD for coliform bacteria analysis and ranged from a minimum of 5.66% to a maximum of 186.27%.

### I.B. Accuracy

The measure of accuracy was accomplished by using internal laboratory spikes for metal analyses performed by the laboratory and readings of calibration standards taken from the sondes. Accuracy was quantified as the percent recovery from analysis of a known concentration. This was accomplished using internal lab spikes and calculated on a per batch basis and sonde measurement of calibration standards. The data quality objective for accuracy for all measurements in the Protocol is:

%Recovery = 85% to 115%

Other checks for accuracy were accomplished through close adherence to instrument calibration procedures. All duplicate sample collection results are presented in Appendix C, Table C-8 through C-13.

Accuracy readings were collected after duplicate readings had been taken and the sonde and probes were cleaned. The sonde was placed in known (spiked) standards and the sonde parameter reading in the standard (spike) was recorded on the field data sheets to measure accuracy.

- **Specific Conductance –** All of the possible 88 accuracy readings were taken for specific conductance during the 2012 monitoring season. None of the spiked specific conductance readings for accuracy exceeded the 85 to 115% recovery range.

- **pH –** All of the possible 88 accuracy readings were taken for pH during the 2012 monitoring season. None of the spiked pH readings for accuracy exceeded the 85 to 115% recovery range.

- **Turbidity –** All of the possible 88 accuracy readings were taken for turbidity during the 2012 monitoring season. None of the spiked turbidity readings for accuracy exceeded the accuracy range of 85 to 115%.

- **Dissolved Oxygen** – All of the possible 88 accuracy readings were taken for dissolved oxygen during the 2012 monitoring season. One spiked dissolved oxygen readings for accuracy exceeded the 85 to 115% recovery range. Overton dissolved accuracy on August 9 was 5.98 mg/L for the sonde reading with a calibration point of 7.94 mg/L for a %R of 75.31%.

## I.C. Representativeness

- **Continuous Water Quality Data**
  Representativeness was addressed by adhering to the Protocol procedures (e.g., collecting a composite sample), manufacturer calibration procedures, and a sampling plan which describes appropriate location, time, and conditions for data collection. Any condition that may result in a "non-representative sample" was noted on the field data sheet and was evaluated during the data review process. A review of the field data sheets (Appendix E) revealed several "conditions" which resulted in "non-representative" data points being collected.

  Temperature and pH were found to be consistent and stable during the monitoring program and minimally affected by monitored environmental conditions of the river. Environmental conditions resulting in non-representative data being collected in the Platte River included burial of the sonde in sediment, sediment accumulation in the

specific conductance measurement cell, air bubble accumulation in the specific conductance measurement cell, algal growth on the optical aperture of the dissolved oxygen and turbidity probes, and insect colonization on all the probes, particularly the dissolved oxygen and turbidity probes. The raw data in combination with the field data sheets were reviewed to determine data "non-representative" of the Platte River. Any data that was non-representative was not included in the summary data.

- **Discrete Water Quality Data (Metals)**
  Representativeness, accuracy, and completeness were assessed by the collecting field/equipment blanks during each of the four discrete water sampling events. The analytical results for the blanks were used to assess cleaning of sampling equipment between locations and container and preservative contamination. One field/equipment blanks were collected and submitted for analytical analysis. No positive detections of analytes were reported in the field blanks (Appendix C, Table C-14).

- **Discrete Water Quality Data (*E. coli*)**
  Representativeness, accuracy, and completeness were assessed by collecting field/equipment blanks during each of the six discrete water sampling events. The analytical results for the blanks were used to assess cleaning of sampling equipment between locations and container and preservative contamination. Six field/equipment blanks were collected and submitted for analytical analysis. No positive detections of analytes were reported in the field blanks (Appendix C, Table C-15 through C-20)

## I.D. Comparability

Comparability of the data can be affected by several factors, including changes in sample locations, parameters, collection, or analytical techniques, etc. Quality assurance procedures were incorporated throughout the Protocol to help assure that comparable data was obtained. These quality assurance procedures included written descriptions of all sample locations; assignment of sampling responsibilities to the same personnel or the appropriate training for new personnel; establishment of a set parameter list; and description of data collection, analysis, and assessment procedures. Adherence to these procedures was closely evaluated during the data quality review process. One factor was noted during the data quality review process that affected the comparability of the data.

- The data sonde at the Louisville monitoring location was initially deployed at the south end of the Platte River Bridge from 12 September to 10 October. On 10 October the sonde was moved and deployed from the north end of the bridge until the end of the monitoring period on 7 December. The specific conductivity of the Platte River is demonstrably different between the north and south sides of the wetted channels and the data is not comparable. On the south side of the River specific conductivity ranged from 0.670 to 1.638 mS/cm and averaged 1.120 mS/cm from 12 September to 10 October. The north side of the River specific conductivity ranged from 0.251 to 0.722 mS/cm and averaged 0.469 mS/cm from 10 October to 7 December.

## I.E. Completeness

Completeness refers to the amount of data necessary to meet the monitoring objectives. To help ensure that the designed monitoring data and water samples were collected, a sampling schedule was prepared and distributed. An inventory and a review process were implemented to maintain data collected, and routinely checked for potential errors, missing data, and missing information on field data sheets. It was the responsibility of the sample collector to make sure field data sheets were completely and accurately filled out and to report missing data from the sondes.

The data completeness necessary to meet the monitoring objectives identified in the 2012 Annual Water Quality Monitoring Plan (EA 2012) were not met. Incomplete or no water quality data was collected at the following monitoring locations.

- Lexington. No water quality data (DO, temperature, pH, specific conductivity, and turbidity) was collected during the monitoring period of 9 August to 7 December2012. Discharge in the Platte River at Lexington was too low during the monitoring period and did not provide sufficient depth for complete inundation of the sonde and it was not deployed.
- Duncan. No water quality data (DO, temperature, pH, specific conductivity, and turbidity) was collected during the monitoring period of 9 August to 7 December 2012. Discharge in the Platte River at Duncan was very low to none during the monitoring period and did not provide sufficient depth for complete inundation of the sonde and it was not deployed.
- Odessa. From 2 October through 11 October no water quality data was collected at the Odessa monitoring location. Discharge in the Platte River during this time period was very low and did not provide sufficient depth for sonde deployment.
- Kearney. From 13 September through 19 September no water quality data was collected at the Kearney monitoring location. Discharge in the Platte River during this time period was very low and did not provide sufficient depth for sonde deployment.

## I.F. Deviations from Methods and Procedures

No deviation from the methods and procedures in the Platte River water quality monitoring Protocols were noted in 2012.

| Acronym List | |
|---|---|
| %R = Percent Recovery | MDL = Method Detection Limit |
| °C = degrees Celsius | mg/L = Milligrams per liter |

# APPENDIX D

Photo Log

1. MS-5 calibration of standards (pH, specific conductance, turbidity, dissolved oxygen).

2. No deployment because of no flow in the Platte River near Duncan, NE.

3. MS-5 sonde deployment from bridge into low water levels in the Platte River near Grand Island, NE.

4. MS-5 sonde deployment from bridge into the Platte River near Shelton, NE.

5. MS-5 sonde deployment using earth anchor into the Platte River near Kearney, NE.

6. Low turbidity levels during normal flow near Kearney, NE.

7. High turbidity levels during J-2 generation discharge near Kearney, NE.

8. MS-5sonde deployment from bridge into low water levels in the Platte River near Kearney, NE.

9. Island building in the Platte River near Kearney, NE.

10. Sediment Augmentation in the Platte River at Cottonwood Ranch.

11. No deployment because of low flow in the Platte River near Lexington, NE.

12. Biofouling on the MS-5.

13. Sand packed into MS-5 PVC casing.

Platte River Recovery Implementation Program

Water Quality Monitoring

Continuous Water Quality Sonde Record

# Duncan

Water quality data was scheduled to be collected at Duncan from 12 September to 7 December, 2012 to monitor a major Program-action effect on Platte River water quality.

No water quality data was collected during this time period because at the Platte River Duncan monitoring location there was either a.) No discharge (dry) or b.) Flow was too low to permit full inundation of the data sonde.

Platte River Recovery Implementation Program

Water Quality Monitoring

Continuous Water Quality Sonde Record

# Lexington

Water quality data was scheduled to be collected at Lexington from 12 September to 7 December, 2012 to monitor a major Program-action effect on Platte River water quality.

No water quality data was collected during this time period because at the Platte River Lexington monitoring location there was either a.) No discharge (dry) or b.) Flow was too low to permit full inundation of the data sonde.

New Data File NA

- Mate 2 calibrated to use for bucket tests.
- YSI 556 not reading DO and pH correctly. Will send to manufacture for repair/service.
